UPCOMING EVENTS

Spring Grounds Maintenance Workshops

We are doing it again. Touring the state, bringing you timely-research-based information you can use to manage your turf, trees, flowers, and ornamentals. We are doing 6 full-day workshops throughout Kansas. Each workshop is packed full of presentations and data from several research and extension specialists. You can read more about it by going to the web at www.KSUTurf.com or directly at http://ksuturf.com/GroundsWorkshop.html

You will hear from the researchers who are studying the turf, trees, flowers and ornamentals in Kansas. You will meet other horticulture professionals from your area that can be a source of information and help when needed. Recertification credits for Kansas pesticide applicators will be available. The credits will vary by location. Check www.KSUTurf.com for information about each location.

Feb 23 in Newton (3A - 3 hours; 3B - 3 hours)
Feb 28 in Emporia (3A - 4 hours; 3B - 3 hours)
Mar 4 in Olathe (3A - 3 hours; 3B - 2 hours)
Mar 9 in Salina (3A - 4 hours; 3B - 3 hours)
Mar 10 in Lawrence (3A - 3 hours; 3B - 3 hrs)
Mar 11 in Topeka (3A - 4 hours; 3B - 3 hours)

FRUIT

Pruning Young Fruit Trees

Young fruit trees should be pruned to begin developing a strong structure of the main or scaffold limbs. This will help prevent limb breakage over the years when the scaffolds carry a heavy fruit load. Apple, apricot, cherry, plum and pear trees generally are trained using the central
leader system. The growth pattern for these trees is for a center branch to be dominant.

Peach and nectarine trees are normally pruned using the open center method because they do not have a strong tendency for one shoot or branch to dominate the growth of other shoots or branches. In this system, the tree is pruned to a vase-like pattern with no central leader.

Regardless of the system used, the three to four scaffold branches should:

- Form wide angles (about 60 to 80 degrees) with the trunk.
- Be distributed on different sides of the tree for good balance.
- Be spaced about 6 to 10 inches apart on the trunk with no branch directly opposite or below another. (WU)

**What Fruit Trees to Plant?**

If you’re pondering that question, here are some comments on fruit trees commonly grown in Kansas. Fruit trees are a long-term investment requiring careful thought before purchase. Begin by choosing fruit you will eat, not fruit that looks good in the catalog. Other considerations are outlined below. Space doesn’t allow for a complete list in this newsletter. For more choices, go to the publication "Small- and Tree-Fruit Cultivars" at [http://www.hfrr.ksu.edu/DesktopModules/ViewDocument.aspx?DocumentID=2814](http://www.hfrr.ksu.edu/DesktopModules/ViewDocument.aspx?DocumentID=2814)

You may also request this publication from your local K-State Research and Extension office.

**Apples:** Though we can grow a wide variety of apples in Kansas, pest-free fruit requires an extensive spray program. Apples are normally sprayed from March (dormant spray) until about 2 weeks before harvest. Sprays from April on throughout the growing season are applied at least every two weeks. You need two different varieties of apples to get fruit. Recommended varieties include Jonathan, Gala, Empire, Delicious, Golden Delicious, Jonagold and Granny Smith. Recommended apples that are disease resistant include William's Pride, Enterprise, Priscilla and Redfree.

Planting disease-resistant apples will reduce, but not eliminate, the need for pesticide applications. None of the apple varieties listed above are resistant to the summer apple diseases sooty blotch and flyspeck. Therefore, it may be necessary to periodically apply a fungicide in the summer to suppress these fruit blemishing diseases. Also, all of the varieties listed will require protection from codling moth and other insect damage.

**Cherries:** Sweet cherries (such as Bing) are not well adapted to Kansas, but sour (pie) cherries are. Cherries are borne in June, so relatively few sprays are needed. Only one tree is needed for
fruit on sour cherries. Recommended sour cherries are Montmorency, Meteor and North Star.

**Apricots:** Apricot trees are quite ornamental, which is fortunate because late spring frosts usually eliminate fruit. On average, assume you will get fruit about once every 5 to 10 years. It is best to have two varieties for full production. Recommended varieties include Moorpark, Goldcot, Manchu and Superb.

**Peaches:** Usually a relatively short-lived tree (10 to 12 years) that needs a great deal of pruning to keep productive. Peaches have the same problem with late frosts that apricots do but may not be quite as bad. Only one tree is needed for fruit. Try Intrepid, Early Redhaven, Redhaven, Harken and Reliance. Intrepid blooms later than other peaches and blooms are much more frost resistant.

**Pears:** Pears are tough and are often one of the few trees that survive on an old homestead. Though trees should be sprayed, the chance of getting good fruit without spraying is much better than it is with apples. Usually, two trees are needed to get fruit. Proven pears include Seckel, Moonglow and Duchess.

To learn how to control fruit pests see, “Fruit Pest Control for Home Gardens,” at http://www.ksre.ksu.edu/library/hort2/c592.pdf or available from local K-State Research and Extension offices. (WU)

**ORNAMENTALS**

**Pruning Deciduous Shrubs**

Gardeners are eager to get out and do something in the landscape this time of year. One chore that can be taken care of now is pruning certain shrubs. Often, gardeners approach pruning with trepidation, but it is not as difficult as it may seem. Remember, not all shrubs need to be pruned (i.e., witch hazel), and certain shrubs, which will be identified later, should not be pruned this time of year. Shrubs are pruned to maintain or reduce size, rejuvenate growth, or to remove diseased, dead or damaged branches. Deciduous shrubs are those that lose leaves each winter. Evergreen shrubs maintain foliage all year and include yews and junipers.

Deciduous shrubs are placed into three groups:
- Those that flower in the spring on wood produced last year;
- Those that flower later in the year on current season’s growth; and
- Those that may produce flowers, but those flowers are of little ornamental value.
Shrubs that flower in the spring should not be pruned until immediately after flowering.
Though pruning earlier will not harm the health of the plant, the flowering display will be reduced. Examples of these types of plants include forsythia, lilac and mock orange. Shrubs that bloom on current season’s growth or that do not produce ornamental flowers are best pruned in late winter to early spring. Examples include Rose-of-Sharon, pyracantha, Bumald spirea and Japanese spirea.

Pruning during the spring allows wounds to heal quickly without threat from insects or disease. There is no need to treat pruning cuts with paints or sealers. In fact, some of these products may retard healing. There are three basic methods used in pruning shrubs: thinning, heading back and rejuvenating. Thinning is used to thin out branches from a shrub that is too dense. It is accomplished by removing most of the inward growing twigs by either cutting them back to a larger branch or cutting them back to just above an outward-facing bud. On multi-stemmed shrubs, the oldest canes may be completely removed.

Heading back is done by removing the end of a branch by cutting it back to a bud and is used for either reducing height or keeping a shrub compact. Branches are not cut back to a uniform height because this results in a "witches-broom" effect.

Rejuvenation is the most severe type of pruning and may be used on multi-stem shrubs that have become too large, with too many old branches to justify saving the younger canes. All stems are cut back to 3- to 5-inch stubs. This is not recommended for all shrubs but does work well for spirea, forsythia, pyracantha, ninebark, Russian almond, little leaf mock orange, shrub roses and flowering quince. (WU)

**VEGETABLES**

**Tips for Gardeners New to Growing Transplants**

Following are several tips that can help home gardeners in growing transplants.

Use fluorescent lamps, not incandescent bulbs. Often a south-facing window does not provide enough light to grow strong transplants and therefore supplemental lighting is helpful. Fluorescent lights produce much less heat than incandescent bulbs. This allows fluorescent bulbs to be placed very close to the plants (2 to 4 inches) thereby increasing the amount of light received. This additional light produces stronger plants.

Leave fluorescent lamps on long enough. Young plants do not react to daylength and so lights can be left on as long as desired. Sixteen hours of light each day is usually sufficient. A time clock can be used to automate the process.
Rewet a peat-based media with hot water. Though moist peat will absorb cold water easily, dry peat will not. Hot water overcomes the hydrophobic nature of dry peat. Small batches of media can be mixed with water in a sealable plastic bag to cut down on the mess.

Plants react to movement. Adding a fan to increase air movement on seedlings will cause them to become stockier. However, air movement will not compensate for lack of light. Plants grown under inadequate light will be spindly regardless of air movement. There is no need to run the fan 24 hours a day. A few hours per day will be sufficient. (WU)

**Lettuce**

Though lettuce is most often planted directly from seed in late March to early April it can be started from transplants. Transplants allow lettuce to mature earlier so that it escapes the excessive heat that can lead to a strong flavor and bitterness. Seed should be started 4 to 5 weeks before transplanting. Since transplants are placed at the same time as direct seeding, now would be a good time to begin. Use a seed starting mix and plant shallow as lettuce requires light for germination. A soil temperature of 70 degrees will encourage germination. However, a cooler temperature of 55 to 60 degrees should be used once the plants emerge.

Time to maturity varies depending on the type of lettuce, with leaf lettuce being the quickest followed by bibb, romaine and buttercrunch lettuce. Head or crisphead lettuce is the slowest and is least likely to mature before becoming bitter.

Spacing also varies with type. Leaf lettuce plants are spaced 4 to 6 inches apart, buttercrunch, bibb and romaine are set at 6 to 8 inches and head lettuce should be at least 8 inches apart in the row. Lettuce does not have an extensive root system and requires regular watering if rainfall is lacking.

Fertilize before planting according to soil test. Plants should also be sidedressed when about 1/3 grown. Sidedressing is done with fertilizers that have more nitrogen than phosphorus and potassium. Use 1/3 cup of nitrate of soda (16-0-0) or 1/4 cup of a 27-3-3, 29-5-4 or similar fertilizer per 10 feet of row. The latter fertilizers are lawn fertilizers but will work well for sidedressing as long as they do not contain weed killers or weed preventers. (WU)

**Useful Gardening Publications**

The “Fertilizing Gardens in Kansas” publication has been completely redone with new artwork and updated information. The much more attractive 12-page publication has information on soil testing, fertilizers, composting and pH. Information on changing the pH and fertilizing specific
vegetables and fruit is also given. You can find this publication at your local K-State Research and Extension office or download it at [http://www.ksre.ksu.edu/library/hort2/mf2320.pdf](http://www.ksre.ksu.edu/library/hort2/mf2320.pdf).

Another very helpful publication is the “Vegetable Garden Planting Guide.” Information is given on how much of each vegetable to plant per person, the expected yield, spacing, and days to first harvest. A chart with suggested planting and probable harvest dates is also included. This publication has not been updated in years but the information is timeless. You can find the Vegetable Garden Planting Guide at [http://www.ksre.ksu.edu/library/hort2/mf315.pdf](http://www.ksre.ksu.edu/library/hort2/mf315.pdf) (WU).

**FLOWERS**

**Iris Leaf Spot Control Starts Now**

Now is a good time to begin control measures for iris leaf spot by removing old, dead leaves. Iris leaf spot is a fungus disease that attacks the leaves and occasionally the flower stalks and buds of iris. Infection is favored by wet periods during the spring, and emerging leaves eventually show small (1/8- to 1/4-inch diameter) spots. The borders of these spots are reddish, and surrounding tissue first appears water-soaked, and then yellows. Spots enlarge after flowering and may coalesce. The disease tends to be worse in wet weather and may kill individual leaves. Though the disease will not kill the plant directly, repeated attacks can reduce plant vigor so that the iris may die from other stresses. Spores are passed to nearby plants by wind or splashing water.

Because this disease overwinters in old leaves, removal and destruction of dead leaves will help with control. For plants that had little infection the previous year, this may be all that is needed. Plants that were heavily infected last year should be sprayed with chlorothalonil (Bravado Fungicide, Fertilome Liquid Fungicide, Ortho Garden Disease Control, GardenTech Fungicide Disease Control, Bonide Fungonil, Bravo Flowable Fungicide, Gordon's Multipurpose Fungicide) or myclobutanil (Imunox) starting when leaves appear in the spring. Repeat sprays every seven to 10 days for four to six sprays. Iris leaves are waxy, so be sure to include a spreader-sticker in your spray to ensure good coverage. (WU)

**MISCELLANEOUS**

**Repotting Houseplants**

As outdoor plants break dormancy and start to grow in response to the longer days and warmer
spring temperatures, houseplants usually put on a spurt of growth as well. Eventually, these indoor plants outgrow their containers and need to be repotted. To check if your plants are becoming root bound and need a larger pot, inspect the root system. First, knock the plant out of its pot. Watering several hours before this operation will allow the plant to be removed more easily. On pots that are 8 inches in diameter or less, place one hand over the top of the pot with the stem of the plant passing between two fingers, and turn the plant upside down. Then rap the edge of the pot against a table. The root ball should come away from the pot. On pots that are more than 8 inches in diameter, a bit more encouragement may be needed. Place the pot on its side and rap the top edge of the pot with a rubber mallet. Turn the plant a few degrees, and repeat the procedure until the root ball releases.

Once the plant is free, take a look at the root ball. If you see a clear network of roots, the plant needs to be moved to a larger pot. If the original pot is less than 10 inches, move up an inch in size; if 10 inches or larger, increase the size 2 inches. If the pot has one or several large holes in the bottom for drainage, cover the holes with pot shards (pieces of a broken clay pot) or gravel so that the potting mix is not washed out during watering.

It is essential that the plant sit at the same level it was in the old pot. Add enough potting mix to the bottom of the pot to ensure this. This mix will need to be firmed before the plant is placed on top of it so it doesn’t settle over time. After the plant is placed, fill in around the original root ball with potting soil. Again, firm this soil with a slender stick, or tap the bottom of the pot on the table. If this firming is not done, new soil will be so light and airy that water will tend to move through it rather than through the whole root ball.

Water the plant thoroughly after repotting, but be especially careful not to overwater for about 2 weeks. The new soil tends to stay wet until roots penetrate. Overwatering can lead to rot. Most plants need to be repotted annually though vigorous growers may need to move up sooner. Slow-growing plants may stay in the same pot for more than a year. (WU)
