Video of the Week: Planting a Garden

ANNOUNCEMENTS

This Week’s K-State Garden Hour Webinar: Raised Bed & Container Gardening
Wednesday, April 7; Noon – 1:00pm CST
Presented by: Travis Carmichael, Lyon County Extension Horticulture Agent

Join this free gardening webinar the first and third Wednesday of every month. Recordings are made available online, and a one-time registration is required participate in the live webinar series. To register, see upcoming webinars, and view previous webinars, visit: http://ksre-learn.com/KStateGardenHour

REMINDEERS

1. Remove dead canes from raspberries and blackberries.
2. This is a good time to plant cabbage, broccoli, cauliflower transplants as well as lettuce, kale, beets, carrots and swiss chard if you haven’t done so yet.

TURFGRASS

Henbit and Chickweed in Lawns

The plant with the little purple flowers that have been showing up in home lawns is called henbit. If you are not sure this is what you have, check the stems. If they are square rather than round, you have henbit. A plant that also is low growing but has round stems and tiny white flowers is chickweed.

Both these plants are winter annuals and start to grow in the fall. They spend the winter as small plants and so most people do not pay much attention to them until they start to flower in the spring. Trying to kill either one at this late stage with a herbicide usually is a waste of time and money. Though plants may be burned back, they will rarely be killed. So what should you do? Remember, these are winter annuals that will die as soon as the weather turns hot. Keep the lawn mowed until nature takes its course.

However, you can do something next fall that will help next spring. Henbit and chickweed usually germinate about mid-October. Spraying with 2,4-D, Weed-B-Gon, Weed Free Zone, Weed Out, or Trimec in late October to early November can go a long way toward eliminating
these plants as they are small and relatively easy to control. Choose a day that is at least 50 degrees F. These herbicides will work at temperatures below 50 degrees but the weeds are killed at a slower rate. You may also use a preemergent herbicide for lawns in late September as long as have not recently put down grass seed. Spraying with the postemergence herbicides mentioned earlier will also catch dandelions which the preemergent herbicides will miss.

Spot treating may be needed in the spring (March) whichever method of control you use but is more likely with the use of preemergent herbicides. Use Weed Free Zone, Speed Zone, Weed Out, Weed-B-Gon, Trimec, or one of the special henbit herbicides early in the spring before they have put on much growth. (Ward Upham)

**FRUIT**

**Fertilizing Grapes**

*Year of Planting:* Apply one-half cup of a 10-10-10, 12-12-12 or similar fertilizer per vine as growth begins in the spring. Repeat after one month. Fertilizers should be spread evenly from the trunk out 3 to 5 feet.

*Second Year:* Apply 1 cup of a 10-10-10, 12-12-12 or similar fertilizer per vine as growth begins in the spring. Fertilizers should be spread evenly from the trunk out 3 to 5 feet.

*Mature Vines (3 years and older):* If the soil test recommends phosphorus and potassium, use a 10-10-10, 12-12-12 or similar fertilizer at the rate of 2 cups per mature vine. Fertilizers should be spread evenly from the trunk out 3 to 5 feet. If, however, there are adequate levels of phosphorus and potassium, add 3/4 cup of a high nitrogen fertilizer such as a 27-3-3, 29-5-4, 30-3-3 or something similar instead of the 10-10-10. Though recommended for lawns, these fertilizers will also work well as long as they do not contain weed killers or crabgrass preventers. Fertilizers should be spread evenly from the trunk out 3 to 5 feet. (Ward Upham)

**Fertilizing the Home Orchard**

Fruit trees benefit from fertilization around the bloom period, but the amount needed varies with the age of the tree. Normally, trees primarily need nitrogen, so the recommendations are for a high nitrogen fertilizer such as a 27-3-3, 29-5-4, 30-3-3 or something similar. Though recommended for lawns, these fertilizers will also work well as long as they do not contain weed killers or crabgrass preventers. Use the following rates:

- Trees 1 to 2 years old, apply one-fourth cup of fertilizer per tree;
- Trees 3 to 4 years old, apply one-half cup per tree;
- Trees 5 to 10 years old, apply 1 to 2 cups per tree;
Trees more than 10 years old, apply 2 to 3 cups.

You may also use nitrate of soda (16-0-0) but double the rate recommended above. If a soil test calls for phosphorus and potassium, use a 10-10-10 but triple the rate.

On apple trees, last year's growth should be 8 to 10 inches, cherries should have 10 to 12 inches, and peaches should equal 12 to 15 inches of terminal growth. If less than this, apply the higher rate of fertilizer, and if more, apply the lesser amount.

Spread all fertilizer evenly on the ground away from the trunk of the tree and to the outer spread of the branches. Water in the fertilizer with at least 1/4 inch of water if rain does not do the job for you. (Ward Upham)

**VEGETABLES**

**Blanching Cauliflower**

Gardeners that haven't grown cauliflower before are often surprised that the heads of most varieties are a yellowish color and not the white they expect. The yellowish hue is a reaction to sunlight. In order to have the heads remain white, the developing heads must be covered to protect them from the sun. This is commonly done by pulling several of the outer leaves over the head when the head is the size of a silver dollar. Hold the leaves in place with a rubber band, tape or soft twine. Plants need to be checked every few days to make sure the curds of the expanding head don't begin to show. There are some varieties that are self-blanching but watch them to make sure the leaves actually do cover the head. Self-blanching varieties are more likely to “work” in cool weather. (Ward Upham)

**ORNAMENTALS**

**There Never Used to be Fruit on Ornamental Pears**

The fruit on ornamental pears is quite small; about the size of a marble. However, it can be very messy if it lands on sidewalks or driveways and people squish the fruit when walking or driving. You may have noticed that ornamental pears are producing fruit much more commonly than they have in the past. Why is this so? A little history is needed in order to understand what has happened.

Ornamental pears used to be called Bradford pears. This was a bit of a misnomer as ‘Bradford’ was a specific variety. Ornamental pears were called Bradfords because this was practically the only variety that people planted. Therefore, if you bought an ornamental pear a number of years ago, it was likely a Bradford. All was well and good until people noticed that Bradfords would fall apart after a number of years due to a weak branching structure. Therefore, nurseries started selling “improved” ornamental pears that were
not Bradfords such as ‘Aristocrat’, ‘Capital’, ‘Redspire’, ‘Chanticleer’ and various other varieties. It was felt that all of these varieties had a stronger branching pattern than ‘Bradford’ but such may not be the case. Both ‘Chanticleer’ and ‘Redspire’ have shown branch breakage. ‘Aristocrat’ does appear to have better branch angles but more time is needed to make a firm recommendation.

Here is the key. Pears usually require cross-pollination in order to fruit. In other words, you must have two different varieties of pear before fruit forms. When all we had were Bradfords, we had no fruit due to a lack of cross-pollination. Now that we have such a mixture of varieties, we will get fruit as long as two different varieties of ornamental pears bloom at the same time and are close enough that bees can work between them.

This formation of fruit can also lead to a second problem. Volunteer trees can come up from the seed contained in the fruit. Therefore, you may see ornamental pears come up in areas where no one planted them. This has become enough of a problem that several states have added ornamental pears to their invasive plant list.

There are products that are sold as fruit preventers such as Florel but timing and air temperature are critical and our results have been mixed. (Ward Upham)

**MISCELLANEOUS**

**Planting Easter Lilies Outside**

Gardeners often hate to throw out Easter Lilies after they finish blooming and may wonder if they can grow outside. Though not reliably hardy in Kansas, many gardeners have success if they follow a few simple rules.

1. After the flowers have faded, remove the flower stalk so that energy does not go into making seed.

2. Keep the plant inside until the danger of frost is past. Keep soil moist but never waterlogged. Don’t allow water to sit in the tray. Continue to fertilize.

3. The pot can be moved outside when frost is no longer a concern. Sinking the pot into the soil up to the brim and placing in dappled shade will help reduce watering. Continue to water and fertilize until the top growth dies down.

4. Choose a sunny, well-drained spot for planting. Good drainage is vital for lilies and so the addition of organic matter is usually necessary for most soils. Till or dig the soil 6 inches deep and add 3 inches of peat moss. Mix the soil and peat moss together. This will form a berm that should drain very well.

5. Plant the bulbs 6 inches deep and 12 to 18 inches apart and water in well. Mulch to conserve moisture. New growth may appear later in the summer or the plant may stay dormant until the following spring.
6. Cover the plants in the fall after the foliage has died down with straw, pine needles, wood chips or other types of mulch to help protect the plant over winter. Use 4 inches of straw or 3 inches of any of the other materials.

7. Uncover the plants in the spring to allow new growth to appear and fertilize according to soil test. (Ward Upham)

**Controlling Grassy Weeds in Broadleaf Plants**

Most gardeners are familiar with herbicides that can be used to eliminate broadleaves from grasses (i.e. dandelions from lawns). However, gardeners may not be as familiar with herbicides that can take grasses out of broadleaf plants like shrubs. There are two major weed killer types labeled for homeowners that are used to kill grassy weeds in broadleaf plants. On the commercial side, the trade names for these products are Fusilade and Poast. Homeowner labeling is more diverse. I have seen Fusilade sold under the names of Ortho "Grass-B-Gon". Poast is sometimes sold to homeowners under the names of Ortho "Grass-B-Gon", "Hi-Yield Grass Killer" and "Monterey Grass Getter." There may be other trade names, too. Fortunately, you can identify the product by the common chemical name listed on the label. Fusilade's common chemical name is fluazifop, and Poast's is sethoxydim.

If you decide to use one of these products, read the label carefully. Often, a crop oil must be added to the spray solution for the herbicide to work well. Some grassy weeds are not controlled such as bromegrass and sandbur. Mature tall fescue also is not controlled though seedling tall fescue is. Established bermudagrass is knocked back but rarely killed.

Though both these products can be used over the top of numerous broadleaf plants (including iris), there are some differences in labeling. For example, if you need to control grasses in vegetables, choose Poast as Fusilade is not labeled for vegetables. However, Poast products cannot be used on all vegetables and the waiting period between spraying and harvest may be so long as to make use impractical. To see a label for one of the products that contain sethoxydim, see [Hi-Yield Grass Killer](http://hnr.k-state.edu/extension/info-center/newsletters/index.html). (Ward Upham)
